(54) Title: HORMONE-MEDIATED METHODS FOR MODULATING EXPRESSION OF EXOGENOUS GENES IN MAMMALIAN SYSTEMS, AND PRODUCTS RELATED THERETO

(57) Abstract

In accordance with the present invention, there are provided various methods for modulating the expression of an exogenous gene in a mammalian subject employing modified ecdysone receptors. Also provided are modified ecdysone receptors, as well as homomeric and heterodimeric receptors containing same, nucleic acids encoding invention modified ecdysone receptors, modified ecdysone response elements, gene transfer vectors, recombinant cells, and transgenic animals containing nucleic acids encoding invention modified ecdysone receptor.

Hormone-Mediated Methods For Modulating Expression Of  
Exogenous Genes In Mammalian Systems, and Products  
Related Thereto

FIELD OF THE INVENTION

The present invention relates to methods in the field of recombinant DNA technology, and products related thereto. More particularly, the invention relates to  
5 methods and products for modulating the expression of exogenous genes in mammalian systems.

BACKGROUND OF THE INVENTION

The steroid/thyroid hormone receptors comprise a superfamily of ligand-dependent transcription factors that  
10 play a crucial role in mediating changes in cell fate and function (Evans, R.M., Science 240:889-895 (1988)). The receptors transduce extracellular hormonal signals to target genes that contain specific enhancer sequences referred to as hormone response elements (HREs) Evans,  
15 (1988); Green and Chambon, Trends Genet. 4:309-314 (1988); Yamamoto, K.R., Annu. Rev. Genet. 19:209-252 (1985)). Each receptor recognizes its own HRE, assuring that a distinct response is triggered by each hormonal signal. Together the collection of related transcription factors and their  
20 cognate response elements provides a unique opportunity to control gene expression.

The DNA binding domain of each member of the steroid/thyroid superfamily of receptors has 66-68 amino acids. Twenty of these, including nine cysteines, are  
25 conserved throughout the family. The modular structure of members of this receptor superfamily allows the exchange of homologous domains between receptors to create functional chimeras. This strategy was used to demonstrate that the DNA binding domain is solely responsible for the specific  
30 recognition of the HRE in vivo (Green and Chambon, Nature

325:75-78 (1987); Giguère et al., Nature 330:624-629 (1987); Petkovich et al., Nature 330:444-450 (1987); Kumar et al., Cell 51:941-951 (1987); Umesono et al., Nature 336:262-265 (1988); Thompson and Evans, Proc. Natl. Acad. Sci. U.S.A. 86:3494-3498 (1989) and in vitro (Kumar and Chambon, Cell 55:145-156 (1988)). By analogy with the proposed structure for Xenopus transcription factor IIIA (Miller et al., EMBO J. 4:1609-1614 (1985)), the invariant cysteines are thought to form two "zinc fingers" that mediate the DNA binding function (Hollenberg and Evans, Cell 55:899-906 (1988)). Involvement of these cysteines in Zn(II) coordination is supported by extended X-ray absorption fine structure (Freedman et al., Nature 334:543-546 (1988)), and DNA binding by point mutagenesis experiments (Hollenberg and Evans, (1988)); Severne et al., EMBO J. 7:2503-2508 (1988)).

The HREs are in fact structurally related but functionally distinct. The glucocorticoid receptor response element (GRE), estrogen receptor response element (ERE), and thyroid hormone receptor response element (TRE) have been characterized in detail. These particular response elements have been found to have a palindromic pair of hexameric "half-sites" (Evans, (1988); Green and Chambon, (1988)). With optimized pseudo- or consensus response elements, only two nucleotides per half-site differ between GRE and ERE (Klock et al., Nature 329:734-736 (1987)). On the other hand, EREs and TREs have identical half-sites but the number of nucleotide spacers between the two half sites is different (Glass et al., Cell 54:313-323 (1988)).

In contrast to response elements having the palindromic sequence motif, the following hormone receptors typically recognize response elements having two half-sites in a direct-repeat (DR) sequence motif: RXR, RAR, COUP-TF, PPAR, and the like (see, e.g., Mangelsdorf et al., The

Retinoids: Biology, Chemistry, and Medicine, 2nd Edition, Raven Press, Ltd., New York, 1994, Chapter 8). Thus at least three distinct means are used to achieve HRE diversity: 1) binding site specificity for a particular  
5 half-site; 2) nucleotide spacing between the two half-sites; and 3) the orientation of the half-sites to one another.

In insect systems, a pulse of the steroid hormone ecdysone triggers metamorphosis in Drosophila melanogaster  
10 showing genomic effects, such as chromosomal puffing, within minutes of hormone addition. Mediating this response in insects is the functional ecdysone receptor, a heterodimer of the ecdysone receptor (EcR) and the product of the ultraspiracle gene (USP) (Yao et al. (1993) Nature  
15 366, 476-479; and Yao et al. (1992) Cell 71, 63-72). Responsiveness to an insect ecdysteroid can be recreated in cultured mammalian cells by co-transfection of EcR, USP, an ecdysone responsive reporter, and treatment with ecdysone or the synthetic analog muristerone A.

20 In the field of genetic engineering, precise control of gene expression is an invaluable tool in studying, manipulating and controlling development and other physiological processes. For example applications for regulated gene expression in mammalian systems include  
25 inducible gene targeting, overexpression of toxic and teratogenic genes, anti-sense RNA expression, and gene therapy (Jaenisch, R. (1988) Science 240, 1468-1474). For cultured cells, glucocorticoids and other steroids have been used to induce the expression of a desired gene.

30 As another means for controlling gene expression in a mammalian system, an inducible tetracycline regulated system has been devised and utilized in transgenic mice, whereby gene activity is induced in the absence of the antibiotic and repressed in its presence (see, e.g, Gossen

et al. (1992) Proc. Natl. Acad. Sci. 89, 5547-5551; Gossen et al. (1993) TIBS 18, 471-475; Furth et al. (1994) Proc. Natl. Acad. Sci. 91, 9302-9306; and Shockett et al. (1995) Proc. Natl. Acad. Sci. 92, 6522-6526). However, 5 disadvantages of this system include the continuous treatment of tetracycline to repress expression and the slow clearance of antibiotic from bone which interferes with quick and precise induction. While this system has been improved by the recent identification of a mutant 10 tetracycline repressor which acts conversely as an inducible activator, the pharmacokinetics of tetracycline may hinder its use during development when a precise and efficient "on-off" switch is essential (Gossen et al. (1995) Science 268, 1766-1769).

15           Accordingly, there is a need in the art for improved methods to precisely modulate the expression of exogenous genes in mammalian subjects.

#### BRIEF DESCRIPTION OF THE INVENTION

In accordance with the present invention, there 20 are provided various methods for modulating the expression of an exogenous gene in a mammalian subject. The invention method is useful in a wide variety of applications where inducible in vivo expression of an exogenous gene is desired, such as in vivo therapeutic methods for delivering 25 recombinant proteins into a variety of cells within a patient.

Unlike prior art tetracycline based strategies, transferring ecdysone responsiveness to mammalian cells takes advantage of a naturally evolved steroid inducible 30 system. Advantages of ecdysteroid use include the lipophilic nature of the compounds (which provides efficient penetrance thereof into all tissues, including the brain), short half-lives (which allow for precise and

potent inductions), and favorable pharmacokinetics that prevent storage and expedite clearance.

In accordance with another embodiment of the present invention, there are provided modified ecdysone  
5 receptors, which can be in the form of homodimeric species or heterodimeric species comprising at least one silent partner of the steroid/thyroid superfamily of receptors, along with an invention modified ecdysone receptor. Invention modified ecdysone receptors are useful, for  
10 example, in methods for modulating expression of an exogenous gene in a mammalian subject.

In accordance with additional embodiments of the present invention, there are provided nucleic acids encoding invention modified ecdysone receptors, modified  
15 ecdysone receptor response elements, gene transfer vectors, recombinant cells, and transgenic animals containing nucleic acid encoding invention modified ecdysone receptor.

#### BRIEF DESCRIPTION OF THE FIGURES

Figures 1A - 1D show the optimization of  
20 ecdysone responsiveness using various combinations of USP or RXR with different modified EcRs. In Figure 1A, the numerical values on both sides of the figure are on the same scale, with the GECR/RXR value repeated for clarity. Darkened and stripped bars represent reporter activity with  
25 no hormone or 1 $\mu$ M muristerone A, respectively.

Figure 1B shows FXR and VpEcR activity on ecdysone response element (EcRE) and a hybrid ecdysone/glucocorticoid response element (E/GRE) responsive  
30 reporters. VpEcR, VgEcR, and control transfection without receptors were treated with 1 $\mu$ M muristerone. FXR transfections were treated with 50 $\mu$ M Juvenile Hormone III (Sigma). Darkened and stripped bars represent reporter

and favorable pharmacokinetics that expedite clearance.

ence with another embodiment of the there are provided modified ecdysone be in the form of homodimeric species species comprising at least one silent oid/thyroid superfamily of receptors, ention modified ecdysone receptor. 1 ecdysone receptors are useful, for ods for modulating expression of an a mammalian subject.

nce with additional embodiments of the there are provided nucleic acids modified ecdysone receptors, modified sponse elements, gene transfer vectors, and transgenic animals containing invention modified ecdysone receptor.

#### DESCRIPTION OF THE FIGURES

A - 1D show the optimization of ess using various combinations of USP it modified ECRs. In Figure 1A, the both sides of the figure are on the GEcR/RXR value repeated for clarity. bars represent reporter activity with risterone A, respectively.

shows FXR and VpEcR activity on element (EcRE) and a hybrid oid response element (E/GRE) responsive gEcR, and control transfection without ated with 1 $\mu$ M muristerone. FXR reated with 50 $\mu$ M Juvenile Hormone III and stripped bars represent reporter

activity with no hormone or  $1\mu\text{M}$  muristerone A/ $50\mu\text{M}$  Juvenile Hormone III, respectively.

Figure 1C shows that E/GRE and GRE are non-overlapping response elements. Darkened and stripped bars represent reporter activity with no hormone or  $1\mu\text{M}$  muristerone A/ $1\mu\text{M}$  dexamethasone, respectively.

Figure 1D shows a schematic diagram of modified ecdysone receptors. GEcR is a chimeric receptor containing the N-terminal transactivation domain of GR and the DNA- and ligand-binding domains of EcR. VpEcR is an N-terminal truncation of EcR fused to the activation domain of Vp16. VgEcR is identical to VpEcR except for the following point mutations in the P box of the DNA binding domain: E282G, G283S, and G286V. In the Figure, DBD=DNA binding domain and LBD=ligand binding domain.

Figure 2 shows a schematic diagram of an invention ecdysone inducible gene expression system. After expression of RXR and a modified EcR, the two receptors can heterodimerize and transactivate the ecdysone response element-containing promoter in the presence of hormone. The ecdysone response elements are placed upstream of a minimal promoter (i.e., an enhancerless promoter) which can drive the expression of any exogenous cDNA.

Figure 3A shows a dose-dependent activation of N13 cells with muristerone. N13 cells were grown with varying concentrations of muristerone for 36 hours and then assayed for  $\beta$ -galact. dase activity (open squares) by standard ONPG assay and for luciferase activity (closed circles). Figure 3B shows the time-course of luciferase activity of N13 cells treated with hormone. N13 cells were grown in separate wells in the presence of  $1\mu\text{M}$  muristerone, harvested at varying times, and assayed for luciferase activity as described in Example 3.

Figure 4 shows muristerone activity in mice as described in Example 4.

#### DETAILED DESCRIPTION OF THE INVENTION

In accordance with the present invention, there  
5 are provided methods for modulating the expression of an  
exogenous gene in a mammalian subject containing:

- (i) a DNA construct comprising said exogenous  
gene under the control of an ecdysone  
response element; and
- 10 (ii) a modified ecdysone receptor which, in the  
presence of a ligand therefor, and  
optionally in the further presence of a  
receptor capable of acting as a silent  
partner therefor, binds to said ecdysone  
15 response element;

said method comprising administering to said  
subject an effective amount of a ligand for said modified  
ecdysone receptor; wherein said ligand is not normally  
present in the cells of said subject; and wherein said  
20 ligand is not toxic to said subject.

Thus, in accordance with the present invention  
the insect molting hormone, ecdysone, is advantageously  
employed as a regulated inducer of gene expression in  
mammalian systems, i.e., background levels of expression  
25 are substantially zero in the absence of conditions  
required for induction. It has been found that optimized  
promoters containing a novel modified ecdysone response  
element in conjunction with an invention modified ecdysone  
receptor (preferably having an altered DNA binding  
30 specificity) provide an extremely powerful and specific  
inducible mammalian expression system. The low basal  
activity of the invention expression system is  
advantageously suitable for the expression of transcription  
factors and toxic genes. The excellent dose response and

induction rate characteristics of the invention inducible expression system allow for precise control of both the degree and duration of induction of a desired gene.

Since the invention method provides for regulated  
5 gene expression by an exogenous non-mammalian inducer, it can be advantageously employed in a variety of in vivo and in vitro mammalian expression systems. For example, inducible expression of cre recombinase in transgenic mammals, in accordance with invention methods, would enable  
10 those of skill in the art to accomplish temporally specific inducible gene targeting of the adult or the developing embryo (O'Gorman et al. (1991) Science 251, 1351-1355).

As employed herein, the terms "modulate" and "modulating" refer to the ability of a given  
15 ligand/receptor complex to effect transactivation of transcription of an exogenous gene, relative to such ability of said receptor in the absence of ligand. The actual effect of complex formation on the transactivation activity of a receptor will vary depending on the specific  
20 receptor species which are part of the ligand/receptor complex, and on the response element with which the ligand/receptor complex interacts.

As used herein, when referring to genes, the phrase "exogenous to said mammalian subject" or simply  
25 "exogenous" refers to any gene wherein the gene product is not naturally expressed in the particular cell where expression is desired. For example, exogenous genes can be either natural or synthetic wild type genes and therapeutic genes, which are introduced into the subject in the form of  
30 DNA or RNA. The gene of interest can be introduced into target cells (for in vitro applications), or the gene of interest can be introduced directly into a subject, or indirectly introduced by the transfer of transformed cells into a subject.

"Wild type" genes are those that are native to cells of a particular type. Such genes may be undesirably overexpressed, or may not be expressed in biologically significant levels. Thus, for example, while a synthetic  
5 or natural gene coding for human insulin would be exogenous genetic material to a yeast cell (since yeast cells do not naturally contain insulin genes), a human insulin gene inserted into a human skin fibroblast cell would be a wild type gene with respect to that cell since human skin  
10 fibroblasts contain genetic material encoding human insulin, although human skin fibroblasts do not express human insulin in biologically significant levels.

Wild type genes contemplated for use in the practice of the present invention include genes which  
15 encode a gene product:

the substantial absence of which leads to the occurrence of a non-normal state in said subject; or

a substantial excess of which leads to the  
20 occurrence of a non-normal state in said subject; and the like.

As employed herein, the phrase "therapeutic gene" refers to a gene which imparts a beneficial function to the host cell in which such gene is expressed. Therapeutic  
25 genes are those that are not naturally found in host cells. For example, a synthetic or natural gene coding for wild type human insulin would be therapeutic when inserted into a skin fibroblast cell so as to be expressed in a human host, where the human host is not otherwise capable of  
30 expressing functionally active human insulin in biologically significant levels. In accordance with the methods described herein, therapeutic genes are expressed at a level that provides a therapeutically effective amount of the corresponding therapeutic protein.

Therapeutic genes contemplated for use in the practice of the present invention include genes which encode a gene product:

- 5           which is toxic to the cells in which it is expressed; or
- which imparts a beneficial property to the host subject (e.g., disease resistance, etc); and the like.

Numerous genomic and cDNA nucleic acid sequences  
10 coding for a variety of proteins are well known in the art. Exogenous genetic material useful in the practice of the present invention include genes that encode biologically active proteins of interest, such as, e.g., secretory proteins that can be released from said cell; enzymes that  
15 can metabolize a substrate from a toxic substance to a non-toxic substance, or from an inactive substance to a useful substance; regulatory proteins; cell surface receptors; and the like. Useful genes include genes that encode blood clotting factors such as human factors VIII and IX; genes  
20 that encode hormones such as insulin, parathyroid hormone, luteinizing hormone releasing factor (LHRH), alpha and beta seminal inhibins, and human growth hormone; genes that encode proteins such as enzymes, the absence of which leads to the occurrence of an abnormal state; genes encoding  
25 cytokines or lymphokines such as interferons, granulocytic macrophage colony stimulating factor (GM-CSF), colony stimulating factor-1 (CSF-1), tumor necrosis factor (TNF), and erythropoietin (EPO); genes encoding inhibitor substances such as alpha<sub>1</sub>-antitrypsin; genes encoding  
30 substances that function as drugs, e.g., genes encoding the diphtheria and cholera toxins; and the like.

Typically, nucleic acid sequence information for a desired protein can be located in one of many public access databases, e.g., GENBANK, EMBL, Swiss-Prot, and PIR,  
35 or in many biology related journal publications. Thus,

those of skill in the art have access to nucleic acid sequence information for virtually all known genes. Those of skill in the art can either obtain the corresponding nucleic acid molecule directly from a public depository or the institution that published the sequence. Optionally, once the nucleic acid sequence encoding a desired protein has been ascertained, the skilled artisan can employ routine methods, e.g., polymerase chain reaction (PCR) amplification, to isolate the desired nucleic acid molecule from the appropriate nucleic acid library. Thus, all known nucleic acids encoding proteins of interest are available for use in the methods and products described herein.

As used herein, the terms "mammal" and "mammalian" refer to humans; domesticated animals, e.g., rats, mice, rabbits, canines, felines, and the like; farm animals, e.g., chickens, bovine, porcine and ovine, and the like; and animals of zoological interest, e.g., monkeys and baboons, and the like.

Modified ecdysone receptors contemplated for use in the practice of the present invention comprise:

- an ecdysone ligand binding domain;
- a DNA-binding domain obtained from a DNA-binding protein; and
- an activation domain of a transcription factor,

wherein at least one of said DNA-binding domain or said activation domain is not obtained from a native ecdysone receptor, with the proviso that when said activation domain is derived from a glucocorticoid receptor, said DNA-binding domain is not derived from a glucocorticoid receptor or an E. coli LexA protein. In accordance with the present invention, modified ecdysone receptors function in expression systems, preferably mammalian, to transactivate

gene expression from transcription regulatory regions having ecdysone response elements.

Ecdysone ligand binding domains contemplated for use in the preparation of invention modified ecdysone  
5 receptors are typically derived from the carboxy-terminal portion of native ecdysone receptor and are able to bind ecdysteroids (Koelle et al., Cell, 67:59-77, 1991; and Christopherson et al., PNAS, USA, 89:6314-6318, 1992). Ecdysone ligand binding domains can be functionally located  
10 in either orientation and at various positions within the modified ecdysone receptor of the invention. For example, the ecdysone ligand binding domain can be positioned at either the amino or carboxy terminus of the modified receptor, or therebetween. In a preferred embodiment of  
15 the present invention, the ecdysone ligand binding domain is positioned at the carboxy terminus of the modified receptor (see Figure 1D).

DNA-binding domains contemplated for use in the preparation of invention modified ecdysone receptors are  
20 typically obtained from DNA-binding proteins (e.g., transcription factors). The term "DNA-binding domain" is understood in the art to refer to an amino acid sequence that is able to bind to DNA. As used herein, the term "DNA-binding domain" encompasses a minimal peptide sequence  
25 of a DNA-binding protein, up to the entire length of a DNA-binding protein, so long as the DNA-binding domain functions to associate with a particular response element.

Such DNA-binding domains are known to function heterologously in combination with other functional protein  
30 domains by maintaining the ability to bind the natural DNA recognition sequence (see, e.g., Brent and Ptashne, 1985, Cell, 43:729-736). For example, hormone receptors are known to have interchangeable DNA-binding domains that function in chimeric proteins (see, e.g., U.S. Patent

4,981,784; and Evans, R., 1988, Science, 240:889-895). Thus, similar to the ligand binding domain of invention modified ecdysone receptor, the DNA-binding domain can be positioned at either the carboxy terminus or the amino terminus, or the DNA-binding domain can be positioned between the ligand binding domain and the activation domain. In preferred embodiments of the present invention, the DNA-binding domain is positioned internally between the ligand binding domain and the activation domain.

10 "DNA-binding protein(s)" contemplated for use herein belong to the well-known class of proteins that are able to directly bind DNA and facilitate initiation or repression of transcription. Exemplary DNA-binding proteins contemplated for use herein include transcription control proteins (e.g., transcription factors and the like; 15 Conaway and Conaway, 1994, "Transcription Mechanisms and Regulation", Raven Press Series on Molecular and Cellular Biology, Vol. 3, Raven Press, Ltd., New York, NY).

Transcription factors contemplated for use herein 20 as a source of such DNA binding domains include, e.g., homeobox proteins, zinc finger proteins, hormone receptors, helix-turn-helix proteins, helix-loop-helix proteins, basic-Zip proteins (bZip),  $\beta$ -ribbon factors, and the like. See, for example, Harrison, S., "A Structural Taxonomy of DNA-binding Domains," Nature, 353:715-719. Homeobox DNA-binding proteins suitable for use herein include, for example, HOX, STF-1 (Leonard et al., 1993, Mol. Endo., 7:1275-1283), Antp, Mat  $\alpha$ -2, INV, and the like. See, also, Scott et al. (1989), Biochem. Biophys. Acta, 989:25-48. It 25 has been found that a fragment of 76 amino acids (corresponding to amino acids 140-215 described in Leonard et al., 1993, Mol. Endo., 7:1275-1283) containing the STF-1 homeodomain binds DNA as tightly as wild-type STF-1. Suitable zinc finger DNA-binding proteins for use herein 30 include Zif268, GLI, XFin, and the like. See also, Klug

and Rhodes (1987), Trends Biochem. Sci., 12:464; Jacobs and Michaels (1990), New Biol., 2:583; and Jacobs (1992), EMBO J., 11:4507-4517.

Preferably, the DNA-binding domain used herein is  
5 obtained from a member of the steroid/thyroid superfamily  
of receptors. As used herein, the phrase "member(s) of the  
steroid/thyroid hormone superfamily of receptors" (also  
known as "nuclear receptors" or "intracellular receptors")  
refers to hormone binding proteins that operate as ligand-  
10 dependent transcription factors, including identified  
members of the steroid/thyroid superfamily of receptors for  
which specific ligands have not yet been identified  
(referred to hereinafter as "orphan receptors").

Exemplary members of the steroid/thyroid  
15 superfamily of receptors (including the various isoforms  
thereof) include steroid receptors such as glucocorticoid  
receptor (GR), mineralocorticoid receptor (MR), estrogen  
receptor (ER), progesterone receptor (PR), androgen  
receptor (AR), vitamin D<sub>3</sub> receptor (VDR), and the like; plus  
20 retinoid receptors, such as the various isoforms of  
retinoic acid receptor (e.g., RAR $\alpha$ , RAR $\beta$ , or RAR $\gamma$ ), the  
various isoforms of retinoid X receptor (e.g., RXR $\alpha$ , RXR $\beta$ ,  
or RXR $\gamma$ ), and the like (see, e.g., U.S. Patents 4,981,784;  
5,171,671; and 5,071,773); thyroid receptors (TR), such as  
25 TR $\alpha$ , TR $\beta$ , and the like; insect derived receptors such as  
the ecdysone receptor, and the like; as well as other gene  
products which, by their structure and properties, are  
considered to be members of the superfamily, as defined  
hereinabove, including the various isoforms thereof.  
30 Examples of orphan receptors contemplated for use herein as  
a source of DNA binding domain include HNF4 [see, for  
example, Sladek et al., in *Genes & Development* 4: 2353-2365  
(1990)], the COUP family of receptors [see, for example,  
Miyajima et al., in *Nucleic Acids Research* 16: 11057-11074  
35 (1988), and Wang et al., in *Nature* 340: 163-166 (1989)],

COUP-like receptors and COUP homologs, such as those described by Mlodzik et al., in Cell 60: 211-224 (1990) and Ladias et al., in Science 251: 561-565 (1991), various isoforms of peroxisome proliferator-activated receptors (PPARs; see, for example, Issemann and Green, supra), the insect derived knirps and knirps-related receptors, and the like.

The DNA-binding domains of all members of the steroid/thyroid superfamily of receptors are related, consisting of 66-68 amino acid residues, and possessing about 20 invariant amino acid residues, including nine cysteines. A member of the superfamily can be characterized as a protein which contains these 20 invariant amino acid residues. The highly conserved amino acids of the DNA-binding domain of members of the superfamily are as follows:

```

      Cys - X - X - Cys - X - X - Asp* - X -
      Ala* - X - Gly* - X - Tyr* - X - X -
      X - X - Cys - X - X - Cys - Lys* - X -
20    Phe - Phe - X - Arg* - X - X - X - X -
      X - X - X - X - X - (X - X -) Cys - X -
      X - X - X - X - (X - X - X -) Cys - X -
      X - X - Lys - X - X - Arg - X - X -
      Cys - X - X - Cys - Arg* - X - X -
25    Lys* - Cys - X - X - X - Gly* - Met
      (SEQ ID NO:1);

```

wherein X designates non-conserved amino acids within the DNA-binding domain; an asterisk denotes the amino acid residues which are almost universally conserved, but for which variations have been found in some identified hormone receptors; and the residues enclosed in parenthesis are optional residues (thus, the DNA-binding domain is a minimum of 66 amino acids in length, but can contain several additional residues).

Modification of existing DNA-binding domains to recognize new target recognition sequences is also contemplated herein. For example, in accordance with the present invention, it has been found that the modification  
5 of the "P-box" sequence of DNA-binding domains of members of the steroid/thyroid superfamily of receptors offers unique advantages not present in other chimeric hormone receptors. For example, the modification of a P-box amino acid sequence to preferentially bind to a different hormone  
10 response element half-site than the naturally occurring P-box amino acid sequence can reduce undesired background levels of gene expression. Thus, invention receptors and methods provide the advantage of increasing the selectivity of exogenous gene expression in a particular subject.

15 As used herein, the phrase "P-box amino acid sequence" refers to the proximal element region in a DNA-binding domain of a hormone receptor that typically occurs at the junction of the first zinc finger and the linker region, e.g., at about amino acids 19-23 of the DNA-binding  
20 domain (i.e., amino acids 19-23 of SEQ ID NO:1; see, e.g., Umesono et al. (1989), Cell, 57:1139-1146, Figure 2). Umesono et al. (1989), supra, in Table 1, describe various naturally occurring P-box amino acid sequences for a variety of hormone receptor DNA-binding domains.

25 In one embodiment of the present invention, the P-box sequence of a hormone receptor DNA-binding domain is modified to have a P-box amino acid sequence that differs from the naturally occurring P-box amino acid sequence. In a preferred embodiment of the present invention, the  
30 modified P-box amino acid sequence differs from the naturally occurring P-box amino acid sequence by 3 amino acids.

Preferably, the P-box amino acid sequence is modified so that only the half-site nucleotide sequence

recognized by the DNA-binding domain is changed while not altering the spacing between the two half-sites recognized by the DNA-binding domain. For example, when the DNA-binding domain of the ecdysone receptor is employed in an invention modified ecdysone receptor, the P-box can be modified from the amino acid sequence EGCKG (SEQ ID NO:2; which recognizes the half-site -AGGTCA-) to the amino acid sequence GSCKV (SEQ ID NO:3; which recognizes the half-site sequence -AGAACA-). In a presently preferred embodiment, when the DNA-binding domain of invention modified ecdysone receptor is derived from ecdysone receptor, the P-box amino acid sequence is modified to GSCKV (SEQ ID NO:3).

It has also been found that in vitro evolution methods can be applied to modify and improve existing DNA-binding domains (see, e.g., Devlin et al., 1990, Science, 249:404-406; and Scott and Smith, 1990, Science, 249:386-390).

Activation domains contemplated for use in the preparation of invention modified ecdysone receptor are typically derived from transcription factors and comprise a contiguous sequence of amino acids that functions to activate gene expression when associated with a suitable DNA-binding domain and a suitable ligand binding domain. As with the ligand and DNA-binding domains employed for the preparation of invention modified ecdysone receptors, the activation domain can be positioned at the carboxy terminus, the amino terminus or between the ligand binding domain and the DNA binding domain. In preferred embodiments of present invention, the activation domain is positioned at the amino terminus of the modified ecdysone receptor.

Suitable activation domains can be obtained from a variety of sources, e.g., from the N-terminal region of a member of the steroid/thyroid superfamily of receptors,

from a transcription factor activation domain, such as, for example, VP16 or GAL4 activation domains, and the like. The presently most preferred activation domain contemplated for use in the practice of the present invention is  
5 obtained from the N-terminal region of the VP16 protein.

The presently most preferred modified ecdysone receptors contemplated for use herein are VgEcr (SEQ ID NO:5), VpEcr (SEQ ID NO:7) or GEcr (SEQ ID NO:9), with VgEcr (SEQ ID NO:5) being especially preferred. The  
10 preparation of these modified ecdysone receptors is set forth hereinafter in Example 1.

Invention modified ecdysone receptor proteins can be produced by expressing nucleic acid constructs encoding the chimeric proteins in suitable host cells as described  
15 in Example 1. Recombinant methods of producing desired proteins by introducing an expression construct into appropriate host cells are well-known in the art. Modified ecdysone receptors of the invention can be introduced into a particular subject by direct introduction of the proteins  
20 themselves, by introducing DNA construct(s) encoding the receptor into the subject, or into cells obtained from the subject (wherein the cells are transformed and subsequently returned to the subject).

In a preferred embodiment, invention modified  
25 ecdysone receptors are expressed under the control of a tissue specific promoter. As readily understood by those of skill in the art, the term "tissue specific" refers to the substantially exclusive initiation of transcription in the tissue from which a particular promoter drives  
30 expression of a given gene.

In accordance with one aspect of the present invention, invention modified ecdysone receptors are present in the form of heterodimeric species comprising an

invention modified ecdysone receptor and at least one silent partner of the steroid/thyroid superfamily of receptors. Preferably, the silent partner is a mammalian-derived receptor, with RXR being especially preferred.

5            Silent partners contemplated herein are members of the steroid/thyroid superfamily of receptors which are capable of forming heterodimeric species with the invention modified ecdysone receptor, wherein the silent partner does not directly participate in binding ligand (i.e., only the  
10 modified ecdysone receptor co-partner of the heterodimer binds ligand). The silent partner can either be endogenous to the cells of the subject or can be provided to the subject by introducing DNA construct(s) encoding receptor into the subject. A preferred silent partner for use  
15 herein is RXR. In a particular embodiment of the invention methods, exogenous RXR is provided to said mammalian subject.

          The formation of heterodimeric receptor(s) can modulate the ability of member(s) of the steroid/thyroid  
20 superfamily of receptors to trans-activate transcription of genes maintained under expression control in the presence of ligand for said receptor. For example, formation of a heterodimer of the modified ecdysone receptor with another mammalian hormone receptor promotes the ability of the  
25 modified ecdysone receptor to induce trans-activation activity in the presence of an ecdysone response element.

          In accordance with another aspect of the present invention, invention modified ecdysone receptors are present in the form of homodimeric species comprising a  
30 plurality (i.e., at least two) invention modified ecdysone receptors.

          Ligands contemplated for use herein are compounds which, inside a cell, bind to invention modified ecdysone

receptors, thereby creating a ligand/receptor complex, which in turn can bind to an appropriate response element. The terms "ecdysone" and "ecdysteroid" as interchangeably used herein, are employed herein in the generic sense (in accordance with common usage in the art), referring to a family of ligands with the appropriate binding and transactivation activity (see, for example, Cherbas et al., in Biosynthesis, metabolism and mode of action of invertebrate hormones (ed. J. Hoffmann and M. Porchet), p. 305-322; Springer-Verlag, Berlin). An ecdysone, therefore, is a compound which acts to modulate gene transcription for a gene maintained under the control of an ecdysone response element.

20-Hydroxy-ecdysone (also known as  $\beta$ -ecdysone) is the major naturally occurring ecdysone. Unsubstituted ecdysone (also known as  $\alpha$ -ecdysone) is converted in peripheral tissues to  $\beta$ -ecdysone. Analogs of the naturally occurring ecdysones are also contemplated within the scope of the present invention. Examples of such analogs, commonly referred to as ecdysteroids, include ponasterone A, 26-iodoponasterone A, muristerone A, inokosterone, 26-mesylinokosterone, and the like. Since it has been previously reported that the above-described ecdysones are neither toxic, teratogenic, nor known to affect mammalian physiology, they are ideal candidates for use as inducers in cultured cells and transgenic mammals according to the invention methods.

Ligands contemplated for use in the practice of the present invention are characterized as not normally being present in the cell of the subject, meaning that the ligand is exogenous to the subject. Ecdysteroids, for example, are not naturally present in mammalian systems. Thus, in accordance with the invention method, unless and until an ecdysteroid is administered to the subject, substantially no expression of the desired gene occurs.

An effective amount of ligand contemplated for use in the practice of the present invention is the amount of ligand (i.e., ecdysteroid) required to achieve the desired level of gene expression product. Ligand can be administered in a variety of ways, as are well-known in the art. For example, such ligands can be administered topically, orally, intravenously, intraperitoneally, intravascularly, and the like.

Ecdysone response elements contemplated for use in the practice of the present invention (relating to modulation of the expression of exogenous genes in a subject) include native, as well as modified ecdysone response elements. Since invention modified ecdysone receptors can function as either homodimers or as heterodimers (with a silent partner therefor), any response element that is responsive to an invention modified ecdysone receptor, in the form of a homodimer or heterodimer, is contemplated for use in the invention methods described herein. In a preferred embodiment of the invention, invention modified ecdysone response elements are engineered so as to no longer be capable of binding to a farnesoid hormone receptor (since the mammalian farnesoid hormone receptor is able to bind to native ecdysone receptor response element). Invention modified ecdysone response elements provide low background expression levels of the exogenous gene and increase the selectivity of the gene expression system when used in mammalian systems.

Ecdysone response elements contemplated for use herein are short cis-acting sequences (i.e., having about 12-20 bp) that are required for activation of transcription in response to a suitable ligand, such as ecdysone or muristerone A, associated with a particular hormone receptor. The association of these response elements with otherwise ecdysone-nonresponsive regulatory sequences causes such regulatory sequences to become ecdysone

responsive. Ecdysone response element sequences function in a position- and orientation-independent fashion.

The native ecdysone response element has been previously described, see, e.g., Yao et al., Cell, 71:63-  
5 72, 1992. Modified ecdysone response elements according to present invention comprise two half-sites (in either direct repeat or inverted repeat orientation to one another), separated by a spacer of 0-5 nucleotides. As used herein, the term "half-site" refers to a contiguous 6 nucleotide  
10 sequence that is bound by a particular member of the steroid/thyroid superfamily of receptors. Each half-site is typically separated by a spacer of 0 up to about 5 nucleotides. Typically, two half-sites with a corresponding spacer make up a hormone response element.  
15 Hormone response elements can be incorporated in multiple copies into various transcription regulatory regions.

Preferred modified ecdysone response elements according to the invention comprise, in any order, a first half-site and a second half-site separated by a spacer of  
20 0-5 nucleotides;

wherein the first and second half-sites are inverted with respect to each other;

wherein said first half-site has the sequence:

25 -RGBNNM-,

(or complements thereof) wherein

each R is independently selected from A or G;

each B is independently selected from G, C, or T;

each N is independently selected from A, T, C, or

30 G; and

each M is independently selected from A or C;

with the proviso that at least 4 nucleotides of each -RGBNNM- group of nucleotides are identical with the nucleotides at comparable positions of the sequence

35 -AGGTCA-; and

said second half-site is obtained from a glucocorticoid receptor subfamily response element.

The complement to the -RGBNNM- sequence set forth above is:

5

-YCVNNK-,

wherein

10

each Y is independently selected from T or C;  
each V is independently selected from C, G, or A;  
each N is independently selected from A, T, C, or  
G; and  
each K is independently selected from T or G.

Exemplary first half-sites having the -RGBNNM- motif for use in the invention modified ecdysone response element include, for example, half-sites selected from  
15 -AGGGCA-, -AGTTCA-, -AGGTAA-, -AGGTCA-, -GGTTCA-,  
-GGGTTA-, -GGGTGA-, -AGGTGA-, or -GGGTCA-. A particularly preferred first half-site is -AGTGCA-.

Glucocorticoid receptor subfamily response elements contemplated for use in the practice of the  
20 present invention are response elements having half-sites that are typically bound by glucocorticoid, mineralocorticoid, progesterone or androgen receptors. Suitable half-sites from glucocorticoid receptor subfamily response elements can be selected from the following  
25 sequence (in either orientation):

-RGNNCA-

(or complements thereof such as -YCNNGT-), wherein R, Y and N are as defined above. Exemplary half-sites having the -RGNNCA- motif for use in the invention modified ecdysone  
30 response element include -AGAACA-, -GGAACA-, -AGTTCA-,  
-AGGTCA-, -GGAACA-, -GGTTCA-, -GGGTCA-, -GGGTCA-,  
-AGGTGA-, -GGGTCA-, and the like, as well as complements thereof. Particularly preferred half-sites having the

-RGNNCA- motif include -AGAACA- and -GGAACA-, with -AGAACA- being especially preferred.

When the above-described modified ecdysone response elements are employed to bind invention  
5 heterodimeric receptors, the second half-site is inverted with respect to the first half-site. For example, when describing a single-strand of an invention modified ecdysone response element in the 5'-3' direction, the following general motif can be employed:

10 RGBNNM-(N)<sub>x</sub>-TGNNCY (SEQ ID NO:10),

where x is an integer of 0 up to about 5, with x = 1 being especially preferred. As an alternative orientation to the above described response element motif (SEQ ID NO:10), an invention response element can be described in the 5'-3'  
15 direction as:

RGNNCA-(N)<sub>x</sub>-KNNVCY (SEQ ID NO:11),

where x is an integer of 0 up to about 5, with x = 1 being especially preferred.

In preferred embodiments of the present  
20 invention, the first half-site is obtained from an ecdysone response element and the second half-site is obtained from a hormone response element selected from a glucocorticoid response element, a mineralocorticoid response element, a progesterone response element or an androgen response  
25 element. In a particularly preferred embodiment of the present invention, the first half-site is obtained from an ecdysone response element and the second half-site is obtained from a glucocorticoid response element.

In a particularly preferred embodiment of the  
30 invention modified ecdysone response element, the first

half-site is AGTGCA and said second half-site is TGTTCT. The presently most preferred modified-ecdysone response element for use in the invention methods is:

AGTGCA-N-TGTTCT (SEQ ID NO:12).

5 In another aspect of the invention, when modified ecdysone receptors of the invention exist as homodimers, response elements employed preferably have a direct repeat motif (instead of the above-described inverted repeat motif), as follows:

10 RGBNNM-(N)<sub>x'</sub>-RGBNNM (SEQ ID NO:13),

where R, B, N and M are as previously defined, and x' is an integer of 0 up to about 5, with x' = 3 being especially preferred.

Invention modified ecdysone response elements are  
15 characterized as having substantially no constitutive activity, which refers to the substantial absence of background levels of gene expression initiated by invention modified ecdysone response elements when introduced into mammalian expression systems. Since it has been found that  
20 mammalian farnesoid hormone receptors are able to bind to and transactivate gene expression from native ecdysone response elements, in certain embodiments of the present invention (e.g., where it is desired to avoid farnesoid-mediated background expression), modified ecdysone response  
25 elements are employed.

Presently preferred invention modified ecdysone response elements are further characterized as having substantially no binding affinity for farnesoid X receptor (FXR), i.e., invention response elements are incapable of  
30 binding FXR (which would thereby create undesired background levels of expression). Thus, presently

preferred invention modified ecdysone response elements preferably induce basal levels of expression of substantially zero.

Response elements employed in the practice of the present invention are operably linked to a suitable promoter for expression of exogenous gene product(s). As used herein, the term "promoter" refers to a specific nucleotide sequence recognized by RNA polymerase, the enzyme that initiates RNA synthesis. This sequence is the site at which transcription can be specifically initiated under proper conditions. When exogenous genes, operatively linked to a suitable promoter, are introduced into the cells of a suitable host, expression of the exogenous genes is controlled by the presence of ecdysteroid compounds, which are not normally present in the host cells.

In accordance with another embodiment of the present invention, there are provided methods of inducing the expression of an exogenous gene in a mammalian subject containing:

- (i) a DNA construct comprising an exogenous gene under the control of an ecdysone response element,
- (ii) DNA encoding a modified ecdysone receptor under the control of an inducible promoter; wherein said modified ecdysone receptor, in the presence of a ligand therefor, and optionally in the further presence of a receptor capable of acting as a silent partner therefor, binds to said ecdysone response element, and
- (iii) a ligand for said modified ecdysone receptor;

said method comprising subjecting said subject to conditions suitable to induce expression of said modified ecdysone receptor.

Inducible promoters contemplated for use in the practice of the present invention are transcription regulatory regions that do not function to transcribe mRNA unless inducing conditions are present. Examples of suitable inducible promoters include DNA sequences corresponding to: the E. coli lac operator responsive to IPTG (see Nakamura et al., Cell, 18:1109-1117, 1979); the metallothionein promoter metal-regulatory-elements responsive to heavy-metal (e.g. zinc) induction (see Evans et. al, U.S. Patent No. 4,870,009), the phage T7lac promoter responsive to IPTG (see Studier et al., Meth. Enzymol., 185: 60-89, 1990; and U.S. #4,952,496), the heat-shock promoter, and the like.

In accordance with another embodiment of the present invention, there are provided methods of inducing expression of an exogenous gene in a mammalian subject containing a DNA construct comprising said exogenous gene under the control of an ecdysone response element, said method comprising introducing into said subject:

a modified ecdysone receptor; and  
a ligand for said modified ecdysone receptor,

wherein said receptor, in combination with a ligand therefor, and optionally in the further presence of a receptor capable of acting as a silent partner therefor, binds to said ecdysone response element, activating transcription therefrom.

In accordance with another embodiment of the present invention, there are provided methods for the expression of recombinant products detrimental to a host organism, said method comprising:

transforming suitable host cells with:

- (i) a DNA construct encoding said recombinant product under the control of an ecdysone response element, and
- 5 (ii) DNA encoding a modified ecdysone receptor;

growing said host cells in suitable media; and inducing expression of said recombinant product by introducing into said host cells ligand(s) for said  
10 modified ecdysone receptor, and optionally a receptor capable of acting as a silent partner for said modified ecdysone receptor.

Recombinant products detrimental to a host organism contemplated for expression in accordance with the  
15 present invention include any gene product that functions to confer a toxic effect on the organism. For example, inducible expression of a toxin such as the diptheroid toxin would allow for inducible tissue specific ablation (Ross et al. (1993) Genes and Development 7, 1318-1324).  
20 Thus, the numerous gene products that are known to induce apoptosis in cells expressing such products are contemplated for use herein (see, e.g., Apoptosis, The Molecular Basis of Cell Death, Current Communications In Cell & Molecular Biology, Cold Spring Harbor Laboratory  
25 Press, 1991).

Suitable media contemplated for use in the practice of the present invention include any growth and/or maintenance media, in the substantial absence of ligand(s) which, in combination with an invention modified ecdysone  
30 receptor, is(are) capable of binding to an ecdysone response element.

In accordance with another embodiment of the present invention, there are provided nucleic acids encoding invention modified ecdysone receptors. Invention

nucleic acids can be incorporated into various expression vectors known to those of skill in the art. Preferred nucleic acids encoding modified ecdysone receptors are set forth in SEQ ID NOs:4, 6 and 8, with SEQ ID NO:4 being  
5 especially preferred.

In accordance with another embodiment of the present invention, there are provided gene transfer vectors useful for the introduction of invention constructs into suitable host cells. Such gene transfer vectors comprise  
10 a transcription regulatory region having a minimal promoter (i.e., a promoter region that does not have an enhancer), and an invention modified ecdysone response element, wherein said regulatory region is operatively associated with DNA containing an exogenous gene, and wherein said  
15 modified ecdysone response element is present in multiple copies. The number of copies of response elements can readily be varied by those of skill in the art. For example, transcription regulatory regions can contain from 1 up to about 50 copies of a particular response element,  
20 preferably 2 up to about 25 copies, more preferably 3 up to about 10-15 copies, with about 4-6 copies being especially preferred.

Gene transfer vectors (also referred to as "expression vectors") contemplated for use herein are  
25 recombinant nucleic acid molecules that are used to transport exogenous nucleic acid into cells for expression and/or replication thereof. Expression vectors may be either circular or linear, and are capable of incorporating a variety of nucleic acid constructs therein. Expression  
30 vectors typically come in the form of a plasmid that, upon introduction into an appropriate host cell, results in expression of the inserted DNA.

As used herein, the phrase "transcription regulatory region" refers to the region of a gene or

expression construct that controls the initiation of mRNA transcription. Regulatory regions contemplated for use herein typically comprise at least a minimal promoter in combination with an ecdysone response element. A minimal  
5 promoter, when combined with an enhancer region (e.g., a hormone response element), functions to initiate mRNA transcription in response to a ligand/receptor complex. However, transcription will not occur unless the required inducer (ligand) is present.

10 As used herein, the phrase "operatively associated with" refers to the functional relationship of DNA with regulatory and effector sequences of nucleotides, such as promoters, enhancers, transcriptional and translational stop sites, and other signal sequences. For  
15 example, operative linkage of DNA to a promoter refers to the physical and functional relationship between the DNA and promoter such that the transcription of such DNA is initiated from the promoter by an RNA polymerase that specifically recognizes, binds to and transcribes the DNA.

20 Preferably, the transcription regulatory region further comprises a binding site for an ubiquitous transcription factor. Such a binding site is preferably positioned between the promoter and modified ecdysone response element of the invention. Suitable ubiquitous  
25 transcription factors for use herein are well-known in the art and include, for example, Sp1.

Expression vectors suitable for use in the practice of the present invention are well known to those of skill in the art and include those that are replicable  
30 in eukaryotic cells and/or prokaryotic cells as well as those that remain episomal and those that integrate into the host cell genome. Expression vectors typically further contain other functionally important nucleic acid

sequences, such as expression constructs encoding antibiotic resistance proteins, and the like.

Exemplary eukaryotic expression vectors include eukaryotic constructs, such as the pSV-2 gpt system (Mulligan et al., Nature, 1979, 277:108-114); pBlueSkript (Stratagene, La Jolla, CA), the expression cloning vector described by Genetics Institute (Science, 1985, 228:810-815), and the like. Each of these plasmid vectors are capable of promoting expression of the invention chimeric protein of interest.

Promoters, depending upon the nature of the regulation, may be constitutively or inducibly regulated, or may be tissue-specific (e.g., expressed only in T-cells, endothelial cells, smooth muscle cells, and the like). Exemplary promoters contemplated for use in the practice of the present invention include the SV40 early promoter, the cytomegalovirus (CMV) promoter, the mouse mammary tumor virus (MMTV) steroid-inducible promoter, Moloney murine leukemia virus (MMLV) promoter, elongation factor 1 $\alpha$  (EF1 $\alpha$ ) promoter, albumin promoter, APO A1 promoter, cyclic AMP dependent kinase II (CaMKII) promoter, keratin promoter, CD3 promoter, immunoglobulin light or heavy chain promoters, neurofilament promoter, neuron specific enolase promoter, L7 promoter, CD2 promoter, myosin light chain kinase promoter, HOX gene promoter, thymidine kinase (TK) promoter, RNA Pol II promoter, MYOD promoter, MYF5 promoter, phosphoglycerokinase (PGK) promoter, Stf1 promoter, Low Density Lipoprotein (LDL) promoter, and the like.

Suitable means for introducing (transducing) expression vectors containing invention nucleic acid constructs into host cells to produce transduced recombinant cells (i.e., cells containing recombinant heterologous nucleic acid) are well-known in the art (see,

for review, Friedmann, 1989, Science, 244:1275-1281; Mulligan, 1993, Science, 260:926-932, each of which are incorporated herein by reference in their entirety). Exemplary methods of transduction include, e.g., infection  
5 employing viral vectors (see, e.g., U.S. Patent 4,405,712 and 4,650,764), calcium phosphate transfection (U.S. Patents 4,399,216 and 4,634,665), dextran sulfate transfection, electroporation, lipofection (see, e.g., U.S. Patents 4,394,448 and 4,619,794), cytofection, particle  
10 bead bombardment, and the like. The heterologous nucleic acid can optionally include sequences which allow for its extrachromosomal (i.e., episomal) maintenance, or the heterologous nucleic acid can be donor nucleic acid that integrates into the genome of the host.

15 In a specific embodiment, said gene transfer vector is a viral vector, preferably a retroviral vector. Retroviral vectors are gene transfer plasmids that have an expression construct encoding an heterologous gene residing between two retroviral LTRs. Retroviral vectors typically  
20 contain appropriate packaging signals that enable the retroviral vector, or RNA transcribed using the retroviral vector as a template, to be packaged into a viral virion in an appropriate packaging cell line (see, e.g., U.S. Patent 4,650,764).

25 Suitable retroviral vectors for use herein are described, for example, in U.S. Patents 5,399,346 and 5,252,479; and in WIPO publications WO 92/07573, WO 90/06997, WO 89/05345, WO 92/05266 and WO 92/14829, incorporated herein by reference, which provide a  
30 description of methods for efficiently introducing nucleic acids into human cells using such retroviral vectors. Other retroviral vectors include, for example, mouse mammary tumor virus vectors (e.g., Shackelford et al., 1988, PNAS, USA, 85:9655-9659), and the like.

Various procedures are also well-known in the art for providing helper cells which produce retroviral vector particles which are essentially free of replicating virus. See, for example, U.S. Patent 4,650,764; Miller, Human Gene Therapy, 1:5-14 (1990); Markowitz, et al., Journal of Virology, 61(4):1120-1124 (1988); Watanabe, et al., Molecular and Cellular Biology, 3(12):2241-2249 (1983); Danos, et al., Proc. Natl. Acad. Sci., 85:6460-6464 (1988); and Bosselman, et al., Molecular and Cellular Biology, 7(5):1797-1806 (1987), which disclose procedures for producing viral vectors and helper cells which minimize the chances for producing a viral vector which includes a replicating virus.

Recombinant retroviruses suitable for carrying out the invention methods are produced employing well-known methods for producing retroviral virions. See, for example, U.S. Patent 4,650,764; Miller, Human Gene Therapy, 1:5-14 (1990); Markowitz, et al., Journal of Virology, 61(4):1120-1124 (1988); Watanabe, et al., Molecular and Cellular Biology, 3(12):2241-2249 (1983); Danos, et al., Proc. Natl. Acad. Sci., 85:6460-6464 (1988); and Bosselman, et al., Molecular and Cellular Biology, 7(5):1797-1806 (1987).

In accordance with another embodiment of the present invention, there are provided recombinant cells containing a nucleic acid encoding an invention modified ecdysone receptor. Exemplary eukaryotic cells for introducing invention expression vectors include, e.g., CV-1 cells, P19 cells and NT2/D1 cells (which are derived from human embryo carcinomas), COS cells, mouse L cells, Chinese hamster ovary (CHO) cells, primary human fibroblast cells, human embryonic kidney cells, African green monkey cells, HEK 293 (ATCC accession #CRL 1573; U.S. Patent No. 5,024,939), Ltk<sup>-</sup> cells (ATCC accession #CCL1.3), COS-7 cells (ATCC under accession #CRL 1651), DG44 cells (dhfr<sup>-</sup> CHO

cells; see, e.g., Urlaub et al. (1986) Cell. Molec. Genet. 12: 555), cultured primary tissues, cultured tumor cells, and the like. Presently preferred cells include CV-1 and 293 cells.

5 In accordance with another embodiment of the present invention, there is provided a transgenic mammal containing a nucleic acid encoding an invention modified ecdysone receptor. As used herein, the phrase "transgenic mammal" refers to a mammal that contains one or more  
10 inheritable expression constructs containing a recombinant modified ecdysone receptor transgene and/or an exogenous gene under the transcription control of an invention modified ecdysone response element. Preferably, an invention transgenic mammal also contains one or more  
15 inheritable expression constructs containing a member of the steroid/thyroid superfamily of receptors that functions as a silent partner for modified ecdysone receptor (e.g., RXR).

Methods of making transgenic mammals using a  
20 particular nucleic acid construct are well-known in the art. When preparing invention transgenic animals, it is preferred that two transgenic lines are generated. The first line will express, for example, RXR and a modified EcR (e.g., VpEcR). Tissue specificity is conferred by the  
25 selection of tissue-specific promoters (e.g., T-cell specific) that will then direct the expression of the receptors. A second line contains an ecdysone responsive promoter controlling the expression of an exogenous cDNA.

In a preferred embodiment of the present  
30 invention, an invention transgenic mammal contains one or more expression constructs containing nucleic acid encoding a modified ecdysone receptor, exogenous RXR, and an exogenous gene under the transcription control of an invention modified ecdysone response element. It has been

found that in transgenic mice containing an ecdysone inducible promoter (i.e., an invention modified ecdysone response element) and expressing a modified ecdysone receptor and RXR, muristerone treatment can activate gene  
5 expression. Thus, with tissue specific expression of the modified ecdysone receptor and RXR and timely hormone treatment, inducible gene expression can be achieved with spatial, dosage, and temporal specificity.

In accordance with another embodiment of the  
10 present invention, there are provided methods for inducing expression of an exogenous gene in a transgenic mammal containing a modified ecdysone receptor according to the invention, said method comprising:

introducing into said mammal a DNA construct  
15 encoding an exogenous gene under the transcription control of an ecdysone response element responsive to said modified ecdysone receptor; and

administering to said mammal an amount of  
20 ligand for said modified ecdysone receptor effective to induce expression of said exogenous gene.

As discussed hereinbefore, the modified ecdysone receptor forms a homodimer, or optionally a heterodimer in the  
25 presence of a silent partner of the steroid/thyroid hormone superfamily of receptors, and functions to activate transcription from an expression vector having a response element responsive to the particular homodimer or heterodimer formed.

30 In accordance with another embodiment of the present invention, there are provided methods for the induction of two different genes in a mammalian subject comprising: activating a first exogenous gene employing the invention ecdysone inducible system; and activating a

second gene using a tetracycline inducible system. The invention method for inducing two different genes is particularly advantageous because it permits the temporal, spatial, and dosage specific control of two exogenous  
5 genes.

The tetracycline inducible system is well-known in the art (see, e.g, Gossen et al. (1992) Proc. Natl. Acad. Sci. 89, 5547-5551; Gossen et al. (1993) TIBS 18, 471-475; Furth et al. (1994) Proc. Natl. Acad. Sci. 91, 9302-9306; and Shockett et al. (1995) Proc. Natl. Acad. Sci. 92, 6522-6526).

All U.S. and Foreign Patent publications, textbooks, and journal publications referred to herein are hereby expressly incorporated by reference in their  
15 entirety. The invention will now be described in greater detail by reference to the following non-limiting examples.

#### Example 1

##### Preparation of modified ecdysone receptors

##### Plasmid preparation:

20 The plasmids CMX-EcR, CMX-USP, CMX-FXR, CMX-hRXRa, EcREx5-ΔMTV-Luc, CMX-GEcR, MMTV-luc, and CMX-GR have been previously described (Yao, et al., Nature 366:476-479 (1993) and Forman, et al. Cell 81:687-693 (1995)).

25 The plasmid CMX-VpEcR was constructed by ligation of an EcoRI fragment of psk-EcR and CMX-Vp16.

The plasmid CMX-VgEcR was generated by site-directed mutagenesis of CMX-VpEcR using the Transformer Mutagenesis Kit (Clontech) and the mutagenic  
30 Oligonucleotide (SEQ ID NO:14):

5'-TACAACGCCCTCACCTGTGGATCCTGCAAGGTGTTTCTTTTCGACGCAGC-3'.

Mutagenesis of VpEcr to VgEcr altered the P-box region of the DNA binding domain of ecdysone receptor to resemble that of GR (Umesono and Evans, Cell 57:1139-1146 (1989)).

- 5 The following amino acids in the DNA-binding domain of the ecdysone receptor were altered: E282G, G283S, and G286V (E=glutamate, G=glycine, S=serine, V=valine).

The reporter construct EcREx4-ΔHSP-β-gal was constructed by oligomerizing two annealed oligonucleotides containing the HSP-Ecre (Yao, et al., Nature 366:476-479 (1993)).

EcREx4-Splx3-ΔHSP-βgal was constructed by ligating the following annealed oligonucleotides into the Asp718 site of EcREx4-HSP-β-gal (SEQ ID NO:15):

15 5'-GTACTCCCGGGGCGGGGCTATGCGGGGCGGGGCTAATCGCTAGGGGCGGGGCA-3'

and (SEQ ID NO:16):

5'-GTACTGCCCCGCCCCTAGCGATTAGCCCCGCCCCGCATAGCCCCGCCC  
CGGGA-3'.

ΔHSP is a minimal promoter derived from the Drosophila heat shock promoter with its enhancers deleted.

To generate the construct E/GREx4-ΔMTV-Luc, the following oligonucleotides (SEQ ID NO:17):

5'-AGCTCGATGGACAAGTGCATTGTTCTTTGCTGAA-3';

and (SEQ ID NO:18):

25 5'-AGCTTTCAGCAAGAGAACAATGCACTTGTCCATCG-3',

were annealed, multimerized, and ligated into the HindIII site of  $\Delta$ MTV-Luc. The resulting reporter contained 4 copies of the invention modified ecdysone response element E/GRE.

- 5           To produce the plasmid pRC-ESHB, a BglII/(XhoI) fragment containing ECREx4-Sp1x3- $\Delta$ HSP- $\beta$ -gal was subcloned into BglII/(NotI) digested pRC-CMV (Invitrogen, San Diego, CA), which contains a neomycin resistance gene.

Cell Culture and Transient Transfections:

- 10           CV-1 cells were maintained in DMEM supplemented with 10% Fetal Bovine Serum. Transient transfections were performed using DOTAP transfection reagent (Boehringer-Mannheim). Transfections using  $\beta$ -galactosidase as the reporter were assayed either by Galactolight  
15   luminescent assay (Tropix, Bedford, MA) or by standard liquid ONPG assay (Sigma, St. Louis, MO). The values were normalized by co-transfection of CMX-luciferase. Transfections using luciferase as the reporter were assayed by standard techniques using luciferin and ATP. These  
20   values were normalized by co-transfection of CMX- $\beta$ -galactosidase. Hormone treated cells were treated with ethanol, 50  $\mu$ M Juvenile Hormone III (Sigma), 1 $\mu$ M muristerone A (Zambon, Bresso, IT), or 1 $\mu$ M dexamethasone (Sigma) unless otherwise noted.

- 25           To maximize the sensitivity of the invention ecdysone inducible system, modifications of the ecdysone receptor were made. The N-terminal transactivation domain of the ecdysone receptor was replaced by the corresponding domain of the glucocorticoid receptor (GR), resulting in  
30   the modified ecdysone receptor GEcR (See Figure 1D). CV-1 cells were transfected with the plasmid CMX-GEcR encoding the modified ecdysone receptor as discussed above. After transfection, cells were either treated with ethanol or 1 $\mu$ M muristerone A. This hybrid modified ecdysone receptor

boosted muristerone responsiveness from 3- to 11-fold in a transient transfection assay (Fig. 1A). Replacement of the natural heterodimeric partner for the ecdysone receptor, USP, by its mammalian homologue, the retinoid X receptor (RXR), produced a more potent ligand dependent heterodimer, providing a 34 fold induction (Fig. 1A).

A more potent heterodimer, however, was obtained by combining RXR and VpEcR, an N-terminal truncation of the ecdysone receptor attached to the VP16 activation domain, resulting in a 212 fold induction (Fig. 1A and 1D). Different from most nuclear receptor/VP16 fusion proteins which exhibit high constitutive activity, VpEcR generates ligand dependent superinduction while maintaining a very low basal activity (Underhill et al., Mol. Encod. 8:274-285 (1994) and Perlmann et al., Genes & Devel. 7:1411-1422 (1993)).

In addition, the reporter vector was also modified by inserting consensus binding sites for the ubiquitous transcription factor Sp1 between the minimal promoter and the ecdysone response elements (Kamine et al., Proc. Natl. Acad. Sci. 88:8510-8514 (1991) and Strahle et al., EMBO 7:3389-3395 (1988)). The addition of Sp1 sites to the ecdysone responsive promoter increases the absolute activity 5-fold (Fig. 1A).

25

### Example 2

#### Construction of a novel ecdysone response element

Although no mammalian transcription factors have been shown to have a natural enhancer element like the ecdysone response element, which is composed of two inverted half-sites of the sequence AGGTCA spaced by one nucleotide, it is difficult to preclude such a possibility. The recently cloned farnesoid X receptor (FXR) can very weakly activate certain synthetic promoters containing an

ecdysone response element in response to extremely high concentrations of farnesoids (Forman et al., Cell 81:687-693 (1995)).

In FXR containing cells and in transgenic mice, activation of gene expression by endogenous receptors would create undesirable background levels of reporter protein. To circumvent this potential problem, the DNA binding specificity of VpEcR was altered to mimic that of GR, which binds as a homodimer to an inverted repeat of the sequence AGAACA, spaced by three nucleotides. This altered binding specificity was achieved by mutating three amino acid residues of VpEcR in the P-box of the DNA binding domain, a region previously shown to be essential for DNA sequence recognition (Umesono and Evans, Cell 57:1139-1146 (1989)). This new hybrid modified ecdysone receptor is referred herein as VgEcR and is responsive to a new hybrid response element referred to herein as the E/GRE (SEQ ID NO:12), which contains two different half-site motifs, RGBNMM and RGNMCA, spaced by one nucleotide (Fig. 1B). This new response element is a hybrid between the glucocorticoid response element (GRE) and that of type II nuclear receptors like RXR, EcR, retinoic acid receptor (RAR), thyroid hormone receptor (T3R), etc. Although FXR can activate a promoter containing the wild type ecdysone response element, it cannot activate one containing the E/GRE (Fig 1B; note log scale). The E/GRE reporter is not activated by GR nor does VgEcR activate a dexamethasone responsive promoter (Fig 1C).

### Example 3

#### 30 Assay for Ecdysone responsiveness in stable cell lines

Stable cell lines were generated containing the modified ecdysone receptor VpEcR, a heterodimeric partner (RXR), and an ecdysone inducible reporter (Figure 2). 293 cells were transfected with the following linearized

plasmids, pRC-ESH $\beta$ , EcREx5-AMTV-Luc, CMX-VpEcR, and CMX-hRXRa. The following day, the cells were split 1:10 and were allowed to recover one day prior to selection with 1mg/ml G418 (GIBCO). After 14 days of selection, 14  
5 individual clones were isolated and grown separately in the presence of 0.5mg/ml G418. Of 14 G418 resistant clones, 10 demonstrated differing degrees of muristerone responsiveness.

One of these cell lines, N13, was grown in the  
10 presence or absence of 1 $\mu$ M muristerone for 20 hours. Cell lysates were then assayed for  $\beta$ -galactosidase and luciferase activities as described in Example 1. X-gal staining was performed on the stable cell lines. Cells were fixed briefly with 10% formaldehyde in PBS and then  
15 stained with X-Gal (Molecular Probes, Eugene, OR) for 2 to 6 hours. After 24 hours of treatment with 1 $\mu$ M muristerone, 100% of the cells turned dark blue after 3 hours of staining. Thus, mammalian cells containing the modified ecdysone receptor VpEcR, a heterodimeric partner (RXR), and  
20 a reporter gene construct regulated by a modified ecdysone response element, function to efficiently express an exogenous gene in response to a ligand, e.g., ecdysone.

A dose-response assay was conducted by growing N13 cells with varying concentrations of muristerone for 36  
25 hours and then assaying for  $\beta$ -galactosidase activity (using the well-known ONPG assay), or the cells were assayed for luciferase activity. Dose response curves of stably integrated  $\beta$ -galactosidase and luciferase reporters in N13 cells revealed that inducibility approaching 3 orders of  
30 magnitude can be achieved at a final concentration 10 $\mu$ M muristerone (Figure 3A). One-hundred fold induction was achieved by muristerone concentrations as low as 100nM (Figure 3A).

Finally, the kinetics of muristerone mediated induction was measured. N13 cells were grown in separate wells in the presence of 1 $\mu$ M muristerone, harvested at varying times, and assayed for luciferase activity. 5 Inductions of 100-fold in 3 hrs., 1000 fold in 8 hrs., and maximal effects of 20,000 fold after 20 hours of treatment were observed (Figure 3B). Similar results were observed in stable lines containing CMX-VgEcR and the E/GRE reporters.

10

Example 4Bioavailability and activity of muristerone

In order to use muristerone as a potential hormone in mice, its toxicity and bioavailability was examined. For toxicity studies, adult mice were injected 15 intraperitoneally with 20mg of muristerone A suspended in sesame oil. The mice were then observed for approximately two months. For teratogenic studies, pregnant mice were injected with 20mg of muristerone A suspended in sesame oil and both the mother and pups were observed for three 20 months. The results indicate that muristerone maintains its activity when injected into mice, and that it is neither toxic, teratogenic, nor inactivated by serum binding proteins. In addition to the inert qualities of muristerone (an ecdysone), overexpression of VpEcR and RXR 25 appears not to be toxic.

For muristerone bioavailability studies, adult mice were injected intraperitoneally with sesame oil with or without 10mg of muristerone, and were subsequently sacrificed for serum collection. After twelve hours, blood 30 was drawn from the mice, and the serum was isolated by brief centrifugation of the whole blood. In order to conduct transfection assays to test for muristerone activity, serum from sesame oil injected mice was divided, and half was supplemented with muristerone to a final

concentration of 10 $\mu$ M. The three batches of mouse serum were diluted 1:10 in DMEM and placed onto CV-1 cells transfected with CMX-GEcR, CMX-hRXRa, and EcREx5-DMTV-Luc.

The results are shown in Figure 4 and indicate that serum from muristerone treated mice yielded a luciferase activity comparable to that seen from untreated mouse serum supplemented with 1 $\mu$ M muristerone. The results indicate that single-site injected material should be widely circulated, and that there is little or no blunting of activity due to association with serum proteins.

#### Example 5

##### Muristerone dependent gene expression in transgenic mice

To produce transgenic mice, the following DNA constructs were prepared and subsequently injected into fertilized eggs: CD3-VpEcR, CD3-RXR, ESH $\beta$  (Lee et al., J. Exp. Med. 175:1013-1025 (1992)). Two separate lines of transgenic mice were generated harboring either an ecdysone inducible reporter, ESH $\beta$ , or a T-cell specific expression construct of VpEcR and RXR, respectively. The former are referred to as reporter mice, the latter are referred to as receptor mice, and double transgenic mice are referred to as receptor/reporter mice. Constructs CD3-VpEcR and CD3-RXR were mixed and coinjected, while ESH $\beta$  was injected alone. Primary genotyping was performed by Southern blot analysis and the transmission of transgenic mice was monitored by dot blot analysis. Receptor mice were analyzed for VpEcR and RXR expression by Northern blot analysis of RNA collected from these mice. For Northern blot analysis, 15 $\mu$ g of total RNA obtained from the thymus, and various tissues as a control, was run on a denaturing gel and blotted onto a nitrocellulose membrane. The blot was probed with a radiolabeled  $\beta$ -gal-specific probe and exposed on film for 2 days. These receptor mice were healthy, fertile, and appeared normal by visual inspection.

In addition, the transgene was transferred to the offspring as expected by Mendelian genetics. This data suggests that overexpression of VpEcR and RXR in T-cells is not toxic.

Receptor expressing mice were bred with reporter  
5 mice (containing ESH $\beta$ ) to produce double transgenic  
receptor/reporter mice. Adult receptor/reporter transgenic  
mice (genotype=CD3-VpEcR; CD3-RXR; and ESH $\beta$ ) were injected  
intraperitoneally with sesame oil with or without 10mg of  
muristerone. Subsequently, a Northern blot analysis was  
10 performed on the double transgenic lines using RNA isolated  
48 hours after treatment from various tissues including the  
thymus, brain and liver, to test for the specific induction  
of an ecdysone inducible promoter. The probe used was  
specific to the activity of the ecdysone inducible  
15 promoter. The autoradiograph was exposed for 36 hrs. The  
results of the Northern analysis indicate that muristerone  
treatment of the transgenic mouse containing a T-cell  
specific expression construct of VpEcR and RXR, and the  
ecdysone inducible reporter ESH $\beta$ , caused a significant  
20 induction from an ecdysone inducible promoter in the  
thymus, while low basal activity is observed in its  
absence.

While the invention has been described in detail  
with reference to certain preferred embodiments thereof, it  
25 will be understood that modifications and variations are  
within the spirit and scope of that which is described and  
claimed.

That which is claimed is:

1. A method for modulating the expression of an exogenous gene in a mammalian subject containing:

5 (i) a DNA construct comprising said exogenous gene under the control of an ecdysone response element; and

10 (ii) a modified ecdysone receptor which, in the presence of a ligand therefor, and optionally in the further presence of a receptor capable of acting as a silent partner therefor, binds to said modified ecdysone response element;

said method comprising administering to said subject an effective amount of a ligand for said modified ecdysone receptor; wherein said ligand is not normally  
15 present in the cells of said subject; and wherein said ligand is not toxic to said subject.

2. A method according to claim 1, wherein said ecdysone response element is a modified response element which comprises, in any order, a first half-site and a second half-site separated by a spacer of 0-5 nucleotides;  
5 wherein said first half-site has the sequence:

-RGBNNM-,

wherein

10 each R is independently selected from A or G;  
each B is independently selected from G, C, or T;  
each N is independently selected from A, T, C, or G; and

each M is independently selected from A or C;  
with the proviso that at least 4 nucleotides of each  
15 -RGBNNM- group of nucleotides are identical with the  
nucleotides at comparable positions of the sequence  
-AGGTCA-; and

said second half-site is obtained from a  
glucocorticoid receptor subfamily response element.

3. A method according to claim 2, wherein said  
first half-site is obtained from an ecdysone response  
element and said second half-site is obtained from a  
hormone response element selected from a glucocorticoid  
5 response element, a mineralocorticoid response element, a  
progesterone response element or an androgen response  
element.

4. A method according to claim 2, wherein said  
response element has substantially no binding affinity for  
farnesoid X receptor (FXR).

5. A method according to claim 2, wherein said  
first half-site is obtained from an ecdysone response  
element and said second half-site is obtained from a  
glucocorticoid response element.

6. A method according to claim 5, wherein said  
first half-site is AGTGCA and said second half-site is  
TGTTCT.

7. A method according to claim 6, wherein said  
response element has the sequence AGTGCA-N-TGTTCT.

8. A method according to claim 2, wherein said modified ecdysone receptor comprises:

- an ecdysone ligand binding domain;
- a DNA-binding domain obtained from a DNA-binding protein; and
- an activation domain of a transcription factor,

wherein at least one of said DNA-binding domain or said activation domain is not obtained from a native ecdysone receptor,

with the proviso that when said activation domain is derived from a glucocorticoid receptor, said DNA-binding domain is not derived from a glucocorticoid receptor or an E. coli LexA protein.

9. A method according to claim 8, wherein said modified ecdysone receptor is further characterized as having substantially no constitutive activity in mammalian cells.

10. A method according to claim 9, wherein the DNA-binding domain of said modified ecdysone receptor is derived from a member of the steroid/thyroid hormone superfamily of receptors.

11. A method according to claim 10, wherein said member of the steroid/thyroid hormone superfamily of receptors is selected from: EcR, vitamin D<sub>3</sub> receptor, RAR $\alpha$ , RAR $\beta$ , RAR $\gamma$ , RXR $\alpha$ , RXR $\beta$ , RXR $\gamma$ , TR $\alpha$ , TR $\beta$ , or ER.

12. A method according to claim 11, wherein the DNA-binding domain of the modified ecdysone receptor is characterized as having a P-box amino acid sequence that differs from the P-box amino acid sequence of the naturally occurring DNA-binding domain.

13. A method according to claim 12, wherein said modified P-box amino acid sequence preferentially binds to a different hormone response element half-site than said naturally occurring P-box amino acid sequence.

14. A method according to claim 13, wherein the DNA-binding domain of said modified ecdysone receptor is derived from EcR and the P-box amino acid sequence is GSCKV (SEQ ID NO:3).

15. A method according to claim 8, wherein said activation domain is obtained from a member of the steroid/thyroid hormone superfamily of receptors.

16. A method according to claim 8, wherein said activation domain is selected from a glucocorticoid receptor activation domain, a VP16 activation domain or a GAL4 activation domain.

17. A method according to claim 1, wherein said modified ecdysone receptor is selected from VpEcR, VgEcR or GEcR.

18. A method according to claim 17, wherein said modified ecdysone receptor is VgEcR having the amino acid sequence set forth in SEQ ID NO:5.

19. A method according to claim 1, wherein said receptor capable of acting as a silent partner is RXR.

20. A method according to claim 19, wherein said RXR is exogenous to said mammalian subject.

21. A method according to claim 1, wherein said exogenous gene is a wild type gene and/or therapeutic gene.

22. A method according to claim 21, wherein said wild type gene is selected from genes which encode products:

5           the substantial absence of which leads to the occurrence of a non-normal state in said subject; or

          a substantial excess of which leads to the occurrence of a non-normal state in said subject.

23. A method according to claim 21, wherein said therapeutic gene is selected from those which encode products:

5           which are toxic to the cells in which they are expressed; or

          which impart a beneficial property to said subject.

24. A method of inducing the expression of an exogenous gene in a mammalian subject containing:

5           (i) a DNA construct comprising an exogenous gene under the control of an ecdysone response element,

10           (ii) DNA encoding a modified ecdysone receptor under the control of an inducible promoter; wherein said modified ecdysone receptor, in the presence of a ligand therefor, and optionally in the further presence of a receptor capable of acting as a silent partner therefor, binds to said ecdysone response element, and

15           (iii) a ligand for said modified ecdysone receptor;

          said method comprising subjecting said subject to conditions suitable to induce expression of said modified ecdysone receptor.

25. A method of inducing expression of an exogenous gene in a mammalian subject containing a DNA construct containing said exogenous gene under the control of an ecdysone response element, said method comprising  
5 introducing into said subject:

a modified ecdysone receptor; and

a ligand for said modified ecdysone receptor,

wherein said receptor, in combination with a  
10 ligand therefor, and optionally in the further presence of a receptor capable of acting as a silent partner therefor, binds to said ecdysone response element, activating transcription therefrom.

26. A method for the expression of a recombinant product detrimental to a host organism, said method comprising:

transforming suitable host cells with:

- 5 (i) a DNA construct encoding said recombinant product under the control of an ecdysone response element, and  
(ii) DNA encoding a modified ecdysone receptor;

10 growing said host cells in suitable media; and  
inducing expression of said recombinant product by introducing into said host cells ligand(s) for said modified ecdysone receptor, and optionally a receptor capable of acting as a silent partner for said modified  
15 ecdysone receptor.

27. A modified ecdysone receptor comprising:  
an ecdysone ligand binding domain;  
a DNA-binding domain obtained from a DNA-binding protein; and  
5 an activation domain of a transcription factor,  
wherein at least one of said DNA-binding domain or said activation domain is not obtained from a native ecdysone receptor,  
10 with the proviso that when said activation domain is derived from a glucocorticoid receptor, said DNA-binding domain is not derived from a glucocorticoid receptor or an E. coli LexA protein.

28. A nucleic acid encoding a modified ecdysone receptor according to claim 27.

29. A homomeric receptor comprising a plurality of modified ecdysone receptors according to claim 27.

30. A heterodimeric receptor comprising a modified ecdysone receptor according to claim 27, and at least one silent partner of the steroid/thyroid superfamily of receptors.

31. A heterodimeric receptor according to claim 30, wherein said silent partner is a mammalian-derived receptor.

32. A heterodimeric receptor according to claim 31, wherein said mammalian-derived receptor is RXR.

33. A modified ecdysone receptor response element comprising, in any order, a first half-site and a second half-site separated by a spacer of 1-5 nucleotides; wherein said first half-site has the

5 sequence:

-RGBNNM-,

wherein

each R is independently selected from A or G;  
each B is independently selected from G, C, or T;  
10 each N is independently selected from A, T, C, or G; and

each M is independently selected from A or C;  
with the proviso that at least 4 nucleotides of each -RGBNNM- group of nucleotides are identical with the  
15 nucleotides at comparable positions of the sequence -AGGTCA-; and

said second half-site is obtained from a glucocorticoid receptor subfamily response element.

34. A gene transfer vector comprising a transcription regulatory region having a minimal promoter, and a modified ecdysone response element according to claim 33, wherein said regulatory region is operatively  
5 associated with DNA containing an exogenous gene, and wherein said modified ecdysone response element is present in 1 up to about 6 copies.

35. A vector according to claim 34, wherein said regulatory region further comprises a binding site for a ubiquitous transcription factor.

36. A vector according to claim 35, wherein said binding site is positioned between said promoter and said synthetic ecdysone response element.

37. A vector according to claim 36, wherein said ubiquitous transcription factor is Sp1.

38. A vector according to claim 34, wherein said promoter is tissue-specific.

39. A recombinant cell containing a nucleic acid encoding a modified ecdysone receptor according to claim 28.

40. A transgenic mammal containing a nucleic acid encoding a modified ecdysone receptor according to claim 28.

41. A method for inducing expression of an exogenous gene in a transgenic mammal according to claim 40, said method comprising:

5           introducing into said mammal a DNA construct encoding an exogenous gene under the transcription control of an ecdysone response element responsive to said modified ecdysone receptor; and

10           administering to said mammal an amount of ligand for said modified ecdysone receptor effective to induce expression of said exogenous gene.

42. The method according to claim 41, wherein said modified ecdysone receptor forms a heterodimer with a silent partner of the steroid/thyroid hormone superfamily of receptors.

# INTERNATIONAL SEARCH REPORT

International application No.

PCT/US 97/05330

Box I (Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet))

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.:  
because they relate to subject matter not required to be searched by this Authority, namely:  
Remark: Although claim(s) 1-26, 41, 42 as far as in vivo methods are concerned is(are) directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.
2. ☐ Claims Nos.:  
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:  
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.
